I get the feeling last Friday I got a little bit too enthusiastic regarding this issue. I guess this is because it was the week-end.

Actually even when using the FQDN, it seems like it is not possible to connect 2 different Network Shares stored on the same remote server with different credentials!

But, I could connect 3 different Network Shares stored on the same remote server using 3 different sets of credentials.

How?

By using once the IP address in the "NET USE" command, then the NETBIOS name and then the FQDN, I could connect to 3 different Network Shares stored on the same remote server using 3 different sets of credentials.

Could someone tell me more about how Windows handles that?

Thanks in advance.

Julien.
