That would be an issue which you should talk to the device vendor/BSP vendor about, I would think. The bootloader component, developed by the same people who built the board support package (BSP), for the hardware determines how you can load a new OS into the system. It also, of course, if it is capable of reading a flash card to get that image, determines what the correct format for the flash card is. It might easily be that the bootloader doesn't support FAT32, for example, and that your card, which might be large 1GB or larger, let's say, is formatted, when you do that from Windows XP, with FAT32. All we can do is give you some things that might be wrong, though. The people who wrote the bootloader would have to tell you what's right.

I have been attempting to get Windows CE 6.0 running on a solid state PC(x86). I have read everything I could find, and still could not find anything to resolve this issue. The machine I am trying to load my Windows CE 6.0 Image to doesn't connect to the internet, and it's on the other side of the building(too far to run cables to). So, my only option is to use a flash card. I am wondering if there are any resources out there concerning this topic, I have found very, very little. I have been manually copying my CE Image(nk.bin) to the flash card, and then putting the card in the solid state pc. When the pc begins to load, an error reads "Invalid Disk." Does anyone have any information on this issue? Thanks!
