I'm newbie....

and

i'm so confused after looking through the docs, would anyone please clarify these two concept.....thanks~

SDB operates the specified board and is built with in Eboot~. and, with eboot.bin provided ,we need not to concern the low level drivers any more.

BSP mainly different in processors. so in different boards but with the same processor, we could built up OS with uniform BSP shipped with PB, and add corresponding drivers within the image then the board would operate well.

appreciate again~:)
