Hi Amy,

The thing to do is to open the VB editor in each app in turn, go to Project, References, and see which items are checked. Then check the same ones when using code that controls the app from outside.

In addition, you might need to qualify some variable definitions. For instance, if you are controlling Word from VB6, then if you have an object variable defined as being a Shape, you will need to change this to Word.Shape, so that it doesn't clash with VB6's own Shape object.

That was just an example. I had to add that reference in Access to get the same code I was using in Word to work there, even though there was no hint in the help for either app that a reference was needed for this. So I'd like to find a list of the references you have to have, well, referenced for the various features to work.

Thanks;

Amy

Hi Amy,

Step back a bit. Its not clear what you are trying to achieve. When you are coding from within Word VBA, the Office and Word object references are checked by default. What environment are you working in?

Hi, all;

The help makes it look like you can use Application.FileDialog and other objects as is. But they really don't work unless you load a reference to some version of the office object library.

Is there any listing of what things in the help require references to be loaded, and where these references must be loaded from (and what version(s) of Office they work in)?

Thanks;

Amy
